Stephanie's post is detailed and sound in analysing Abi's ethical duties. As you aptly point out, the selective reporting of good results drives away scientific objectivity even without data falsification. This supports Ravn and Sorensen's (2021) claim that such questionable research practices (QRPs) undermine the trust in scientific results, particularly in the industry-influenced context, where the size of a commercial gain can take precedence over some ethical considerations.

Abi is not solely responsible for cleaning statistics, which involve framing and communicating those results. According to Jeyaraman et al. (2023a), it is not only technical work that professionals dealing with AI and data in practice should be willing to develop; they must actively participate in ethical reasoning. Abi will end up ethically complicit with his silence in the presence of predictable misuse. He is obligated to define risks, limitations, and possible misinterpretations as vividly as possible in his report, particularly in situations where the results might impact the population's health.

You also raise a relevant detail: not having clear legal instructions excuses the quest to behave ethically. As Sand et al. (2022) emphasize, ethical values, including transparency and care for the public, should be prioritised when legal advice is vague or unique to different jurisdictions. Although Whizzz is not a medicine but a consumer good, its health-related concerns should not be less closely monitored, especially when children can use it.

Besides, the Codex Alimentarius highlights the necessity of identifying health hazards in food products. Abi's failure to report unfavourable findings jeopardises consumer safety and undermines the larger regulatory regime that exists to safeguard society.

In conclusion, you are right that Abi should not take a neutral position. Ethical imperatives include transparency, integrity, and foresight. He should also do this knowing that his work has consequences—not only to the client but also to society itself.

Fahad, your post illustrates the moral conflict that Abi is afraid of striking between statistical truth and professional ethics. Even though Abi does not change the initial information, picking and choosing only positive results and obscuring evidence to the contrary constitutes ethical manipulation. Regarding digital health technologies, as Galetsi et al. (2023) emphasise, moral responsibility involves the honest reporting of data and thoughtful communication that may not lead to misleading results, even though data may technically be identical.

Abi is responsible for extending past data accuracy to predicting misuse and taking actions to prevent it. According to Sand et al. (2022), the impact of the received information remains the responsibility of the professionals even in the sphere of health. Nevertheless, Abi must intervene if the manufacturer discloses positive outcomes selectively. This may involve in-house escalation, written disclaimers, or asking for contractual assurances of full disclosure. All these are based on moral responsibility and social safety.

You also correctly point out that biased data reporting related to health issues may infringe on consumer protection laws and harm professional reputation. Čartolovni et al. (2022) outline that clinicians working with AI and data to make medical decisions must respect ethical transparency and refuse to succumb to external influences that may skew the results. Abi must not only provide statistical labor but also ensure that statistics are not used to make commercial benefits at the cost of human health.

To wrap up, Abi will seek to reveal positive and negative results, properly contextualised and with proper limits. Whistleblowing may be morally acceptable when internal complaints are not resolved. Maintaining civic confidence and guarding against vulnerable individuals and groups is his first duty, reaffirming that computing ethics is concerned with data accuracy, integrity, courage, and social responsibility.

Noora, your post is significant in considering the ethical and legal issues relating to Abi's actions as a data professional. I greatly concur with your point: If Abi does not edit raw data, his biased reporting on positive outcomes of Whizzz cereal is a form of ethical manipulation, especially in cases where there is a concern for public health. McLennan et al. (2022) claim that embedded ethics must apply to all the processes of medical AI and data development, including analyses and reporting. Abi neglects the duty of beneficence and contravenes transparency, the essence of ethical computing, by overlooking negative results.

You are correct that transparency and intent are paramount to this dilemma. The technical correctness of Abi analyses cannot be ignored, yet, as Stahl et al. (2022) argue, the organisational and individual responses to ethical questions in AI and data should focus on societal rather than business good. By willingly giving a report that serves a biased story, Abi can succeed in contributing to malice not only in the courts but also ethically.

This is of particular concern to what you said about consumer protection laws. Abi may be indirectly liable when Whizzz is sold based on skewed or partial information. In this situation, it is not just a professional precaution to fully document all methods and restrictions but a moral obligation. This is confirmed by White and Hanley (2023), who demonstrate that digital professionals such as therapists and researchers should be held accountable for everything they produce in the public domain where aspects of interest are concerned.

Abi will have to take a firm step of providing a complete, transparent report and explaining any risks and uncertainties. Otherwise, he ought to resort to independent publication or whistleblower means. Responsible data science is not about not telling lies but rather about being true, keeping people safe, and ensuring that data can benefit the people.
